## EXECUTIVE SUMMARY

Since the popularization of the Internet in 1994, enterprise firewalls have proven an effective defense against security exploits aimed at the network and transport levels. Firewalls with a defined security policy—especially Check Point patented Stateful Inspection firewalls based on INSPECT™ technology, the most intelligent, adaptive inspection technology—defeat a full 90 percent of these attacks. However, 21st Century hackers do more than look for exposed vulnerabilities in the network and transport layers. Today, these technically talented rogues actively attack the application level. For example, crucial services like HTTP (TCP port 80), HTTPS (TCP port 443), RPC (Remote Procedure Calls), and NFS (Network Files Systems) have become primary targets of sophisticated schemes to manipulate applications.

To help network administrators deal with application-level attacks, Check Point security solutions with Application Intelligence™ technology provide a potent combination of attack safeguards and attack blocking tools. These safeguards and blocking tools protect the network's most valuable asset—actual user data. Specifically, Check Point security gateways offer Application Intelligence protections and SmartDefense™ Services to prevent and block attacks using mechanisms such as Validating Compliance to Standards, Validating Expected Usage of Protocols (Protocol Anomaly Detection), Limiting Application Ability to Carry Malicious Data, and Controlling Application-Layer Operations. These mechanisms aid proper usage of Internet resources such as Voice over Internet Protocol (VoIP), Instant Messaging, Peer-to-Peer (P2P) file sharing, Web site scripting, print-sharing operations, and File Transfer Protocol (FTP) uploading, among others.

In addition, Application Intelligence and SmartDefense Services continue to offer industry-leading protection against network- and transport-level attacks with strategies countering IP Fragmentation, Smurfing, Non-TCP Denial of Service (Non-TCP DOS), and Port Scans. Overall, Check Point gateways provide the most proven and comprehensive answer to quickly evolving hacker attacks aimed at the application, network, and transport levels, offering a truly multi-layer security solution.

Check Point Application Intelligence™ is a set of advanced capabilities integrated into Check Point products that detect and prevent application-level attacks.

## INTRODUCTION—APPLICATION-DRIVEN ATTACKS

Firewalls have become the staple of network security architectures, primarily providing access control to network resources, and they have been successfully deployed in the large majority of networks. A major reason for firewall success is that when used to enforce a properly defined security policy, firewalls commonly defeat more than 90 percent of network attacks—a crucial element in providing networks with the reliability required in today's competitive environment. However, while most firewalls provide effective access control, many are not designed to detect and thwart attacks at the application level.

Recognizing this reality, hackers have devised sophisticated attacks designed to circumvent the traditional access control policies enforced by perimeter firewalls. Today's knowledgeable hackers have advanced well past scanning for open ports on firewalls and are now directly targeting applications.

Some of the most serious threats in today's Internet environment come from attacks that attempt to exploit known application vulnerabilities. Of particular interest to hackers are services such as HTTP (TCP port 80) and HTTPS (TCP port 443), which are commonly open in many networks. Access control devices cannot easily detect malicious exploits aimed at these services.

By targeting applications directly, hackers attempt to achieve at least one of several nefarious goals, including:

- Denial of Service to legitimate users (DoS attacks)
- Gaining administrator access to servers or clients
- Gaining access to back-end information databases
- Installing Trojan horse software that bypasses security and enables access to applications

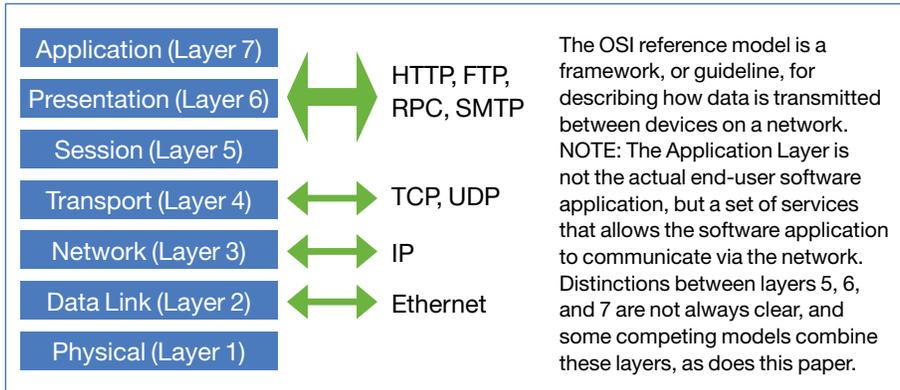

Since application-driven attacks are sophisticated in nature, effective defenses must be equally sophisticated and intelligent. In order to address the increasing threat from application-driven attacks, firewalls must provide comprehensive security on multiple levels. These levels of security should protect against both network and application attacks, while providing robust access control to IT resources.

## APPLICATION INTELLIGENCE—DEFENDING AGAINST TODAY'S THREATS

Many firewalls, particularly those based on Check Point patented Stateful Inspection technology, have maintained successful defense arsenals against network assaults. As a result, a growing number of attacks attempt to exploit vulnerabilities in network applications rather than target the firewall directly. This important shift in attack methodology requires that firewalls provide not only access control and network-level attack protection, but also understand application behavior to protect against application attacks and hazards. Based on INSPECT™, the industry's most intelligent, adaptive inspection technology, Check Point Application Intelligence™ provides this expansive view of network security solutions.

## APPLICATION LAYER SECURITY

### Sample protocols

OSI (Open Systems Interconnection) reference model

The application layer attracts numerous attacks for several reasons. First, it is the layer that contains a hacker's ultimate goal—actual user data. Second, the application layer supports many protocols (HTTP, CIFS, VoIP, SNMP, SMTP, SQL, FTP, DNS, etc.), so it houses numerous potential attack methods. And third, detecting and defending against attacks at the application layer is more difficult than at lower layers because more vulnerabilities arise in this layer.

In order to successfully provide application-layer security, a security solution must address the following four defense strategies.

#### 1. Validate Compliance to Standards

Firewalls must be able to determine whether communications adhere to relevant protocol standards. Violation of standards may be indicative of malicious traffic. Any traffic not adhering to strict protocol or application standards must be closely scrutinized before it is permitted into the network, otherwise business-critical applications may be put at risk. Examples include:

- **Voice over IP (VoIP)**—VoIP traffic is typically supported using H.323, SIP and other protocols. The operation of these protocols can be complex, resulting in numerous communication ports supporting the establishment and maintenance of VoIP calls. Improper enforcement of these protocols can leave VoIP deployment vulnerable to the following hazards:
  - Call redirection—calls intended for the receiver are redirected
  - Stealing calls—the caller pretends to be someone else
  - DoS—preventing legitimate usage of VoIP

Security gateways must ensure that VoIP protocol commands fully conform to appropriate standards and RFCs and that packets are structurally valid and arrive in a valid sequence. In addition, firewalls should examine the contents of packets passing through every allowed port to ensure that they contain proper information.

- **Binary data in HTTP headers**—While the official HTTP standard prohibits binary characters in HTTP headers, the rule is ambiguous and not checked by most firewalls. As a result, many hackers launch attacks by including executable code in HTTP headers. All security gateways should allow for the blocking or flagging of binary characters in HTTP headers and requests.

#### 2. Validate Expected Usage of Protocols (Protocol Anomaly Detection)

Testing for protocol compliance is important, but of equal importance is the capability to determine whether data within protocols adheres to expected usage. In other words, even if a communication stream complies with a protocol standard, the way in which the protocol is being used may be incongruous with what is expected. Examples include:

- **Use of HTTP for peer-to-peer (P2P) communications**—P2P is a communication model in which each party has the same capabilities and either party can initiate a communication session. P2P applications can be divided into two major categories:
  - Instant messaging (IM)—whose main goal is to enable direct online communication between people
  - File sharing networks—whose main goal is to share resources such as storage

P2P communications often utilize TCP port 80, which is usually designated for HTTP traffic and is thus open for outgoing connections. While many proprietary P2P protocols exist, P2P communications often embed themselves within HTTP traffic. In these situations, firewalls that check only for protocol compliance will allow the P2P session (since the session is using standard HTTP). Because commonly expected usage of HTTP is for Web traffic, P2P communications embedded within HTTP traffic should be blocked or flagged by the firewall.

Many organizations want to block or limit P2P traffic for security, bandwidth, and legal reasons. Security issues arise because P2P communications are designed to allow file transfers, chat, games, voice, and email, while bypassing firewalls, virus checking, logging, and tracking. As a result, hackers can use P2P as an attack vector into networks. Security gateways should block unauthorized P2P traffic, or conversely, selectively allow authorized P2P traffic.

- **Directory traversal**—Directory traversal attacks allow a hacker to access files and directories that should be out of reach and can result in running undesired executable code on the Web server by trying to access unauthorized resources. Most of these attacks are based on the “..” notation within a file system. Firewalls should block requests in which the URL contains a directory request that complies with syntax, but does not comply with expected usage. For example, `HTTP://www.server.com/first/second/../../../../` should be blocked because it attempts to go deeper than the root directory.
- **Excessive HTTP header length**—The HTTP standard does not limit header length. However, excessive header length falls outside of normal or expected HTTP usage. Headers of excessive length should be blocked or flagged to reduce the chance of buffer overflows and to limit the size of code that can be inserted using the overflow.

### 3. Limit Applications' Ability to Carry Malicious Data

Even if application-layer communications adhere to protocols, they may still carry data that can potentially harm the system. Therefore, a security gateway must provide mechanisms to limit or control an application's ability to introduce potentially dangerous data or commands into the internal network.

Examples include:

- **Cross-Site Scripting attacks**—Scripts provide a common mechanism for launching attacks against an application. While most scripts are harmless, unsuspecting users can easily and inadvertently execute malicious scripts. These scripts can often be hidden in innocuous looking links or, for instance, disguised as an email card. A common example of malicious scripts appears in Cross-Site Scripting attacks (XSS). Cross-Site Scripting attacks exploit the trust relationship between a user and a Web site by employing specially crafted URLs. The intention of the attack is to steal cookies that contain user identities and credentials or to trick users into supplying their credentials to the attacker. Typically, a Cross-Site Scripting attack is launched by embedding scripts in an HTTP request that the user unwittingly sends to a trusted site. To protect Web servers, the security gateway should provide the capability to detect and block HTTP requests that contain threatening scripting code.
- **Limit or block potentially malicious URLs**—Malicious data can also enter the internal network by embedding itself in URLs. For example, an application such as an email client could automatically execute an HTML-embedded URL. If the URL was malicious, damage to the network or the user's system may occur. Access to potentially malicious URLs should be blocked or limited.
- **Detect and block attack signatures**—Security gateways should perform content filtering on all data streams to detect and block data patterns that are indicative of attacks, worms, etc.

#### 4. Control Application-Layer Operations

Not only can application-layer communications introduce malicious data to a network, the application itself might perform unauthorized operations. A network security solution must have the ability to identify and control such operations by performing “access control” and “legitimate usage” checks. This level of security requires the capability to distinguish, at a granular level, application operations. Examples include:

- **Microsoft Networking Services**—A network security solution can implement security policy using many parameters from CIFS, the Microsoft-based Common Internet File System. CIFS supports, among other capabilities, file- and print-sharing operations. Using these operations as examples, a security gateway should have the capability to differentiate and block file-sharing operations originating from a user or system that does not have appropriate authorization. Conversely, print-sharing operations originating from the same user may be allowed and accepted. Providing a level of security with this granularity requires a thorough understanding of CIFS, as well as the ability to control application-layer protocol components.
- **FTP**—A firewall should place connection restrictions on particular file names and control potentially hazardous FTP commands like PUT, GET, SITE, REST, and MACB. For example, a security policy may require operational restrictions on all files containing the word “payroll.”

## NETWORK AND TRANSPORT LAYERS: NECESSARY FOUNDATION FOR APPLICATION INTELLIGENCE

Application Intelligence, in its purest form, associates itself with application-level defenses. However, in practice many attacks aimed at network applications actually target the network and transport layers. Hackers target these lower layers as a means to access the application layer, and ultimately the application and data itself. Also, by targeting lower layers, attacks can interrupt or deny service to legitimate users and applications (e.g., DoS attacks). For these reasons, Application Intelligence and other network security solutions must address not only the application layer but also network and transport layers.

## NETWORK LAYER SECURITY

Preventing malicious manipulation of network-layer protocols (e.g., IP, ICMP) is a crucial requirement for multi-level security gateways. The most common vehicle for attacks against the network layer is the Internet Protocol (IP), whose set of services resides within this layer. While many network-layer hazards and attacks exist, some examples include:

- **IP Fragmentation**—IP fragmentation can be used to deliver and disguise attacks in order to avoid detection. This technique utilizes the resilience mechanisms inherent in the IP protocol itself (RFC 791 and RFC 815) to intentionally fragment attacks into multiple IP packets so they can circumvent firewalls that do not perform IP fragment reassembly. IP fragmentation can also be used to launch a DoS attack by inundating IP fragment reassembly devices with incomplete fragment sequences.
- **Smurfing (Smurf attack)**—ICMP allows one network node to ping, or send an echo request to, other network nodes to determine their operational status. This capability can be used to perpetrate a “Smurf” DoS attack. The Smurf attack is possible because standard ICMP does not match requests to responses. Therefore, an attacker can send a ping with a spoofed source IP address to an IP broadcast address. The IP broadcast address reaches all IP addresses in a given network. All machines within the pinged network send echo replies to the spoofed, and innocent, IP source. Too many pings and responses can flood the spoofed network and deny access for legitimate traffic. This type of attack can be blocked by dropping replies that don’t match requests, as performed by Check Point’s Stateful ICMP.

## TRANSPORT LAYER SECURITY

As with the network layer, the transport layer and its common protocols (TCP, UDP) provide popular access points for attacks on applications and their data. Examples of transport layer attacks and threats include:

- **Non-TCP DoS**—Non-TCP (e.g., UDP and ICMP) DoS attacks can completely overwhelm mission-critical applications—such as SMTP, HTTP, FTP, etc., which use TCP traffic. Firewalls can protect against these threats by reserving a dedicated portion of the state table for TCP connections. If non-TCP connections attempt to utilize too many resources, TCP connections will be unaffected because they are handled by reserved or dedicated system resources.
- **Port Scan**—A port scan does what the name implies: a hacker scans a range of ports on a target host in hopes of identifying and exploiting weaknesses on running applications. The reconnaissance that a port scan performs is a hazard that can lead to an attack. A security gateway must be able to raise alerts and block or shutdown communications from the source of the scan.

## CONCLUSION

Firewalls have established themselves as the staple of network security infrastructures based on their ability to block attacks at the network level. As a result of firewall success, hackers have developed more sophisticated attack methodologies. The new breed of attacks directly targets applications, often attempting to exploit vulnerabilities inherent in the applications themselves or in the underlying communication protocols. Providing security on multiple levels is required to safeguard corporate networks from these threats. Additionally, multi-level security solutions must protect against both network and application-layer attacks, while providing access control to IT resources.

Check Point Application Intelligence, based on INSPECT, is a set of advanced capabilities integrated into Check Point products that detect and prevent application-level attacks. Check Point solutions provide the industry's most proven and comprehensive answer to the increasing number of attacks directed at critical applications.

# Check Point Multi-Layer Security: Attack Prevention Safeguards and Attacks Blocked

Check Point gateways, including VPN-1, FireWall-1, InterSpect, and Connectra, with SmartDefense, Application Intelligence, and Web Intelligence protection enabled block many attacks and provide numerous attack prevention safeguards. This table lists some of these defenses and organizes them by protocol and OSI model layer.

Note: Check Point continually expands the breadth of defenses provided. This table is a snapshot, not an exhaustive list. Some of the defenses listed under “Attack Prevention Safeguards” are available with SmartDefense updates (through purchase of additional SmartDefense Services). These updates provide additional safeguards to the ones listed in the table. List is current as of April 26, 2005.

Check Point gateways, including VPN-1, FireWall-1, InterSpect, and Connectra, with SmartDefense, Application Intelligence, and Web Intelligence protection enabled block many attacks and provide numerous attack prevention safeguards. This table lists some of these defenses and organizes them by protocol and OSI model layer.

Note: Check Point continually expands the breadth of defenses provided. This table is a snapshot, not an exhaustive list. Some of the defenses listed under “Attack Prevention Safeguards” are available with SmartDefense updates (through purchase of additional SmartDefense Services). These updates provide additional safeguards to the ones listed in the table. List is current as of April 26, 2005.

## ABOUT CHECK POINT SOFTWARE TECHNOLOGIES

Check Point Software Technologies ([www.checkpoint.com](http://www.checkpoint.com)) is the worldwide leader in securing the Internet. It is the confirmed market leader of both the worldwide VPN and firewall markets. Through its Next Generation product line, the company delivers a broad range of intelligent Perimeter, Internal, and Web security solutions that protect business communications and resources for corporate networks and applications, remote employees, branch offices, and partner extranets. The company's Zone Labs ([www.zonelabs.com](http://www.zonelabs.com)) division is one of the most trusted brands in Internet security, creating award-winning endpoint security solutions that protect millions of PCs from hackers, spyware, and data theft. Extending the power of the Check Point solution is its Open Platform for Security (OPSEC™), the industry's framework and alliance for integration and interoperability with "best-of-breed" solutions from more than 350 leading companies. Check Point solutions are sold, integrated, and serviced by a network of more than 2,300 Check Point partners in 92 countries.
